(Received 9 March 2012; published 17 September 2012)

We develop a relativistic variational model for a nematic liquid crystal interacting with an electromagnetic field. The constitutive relation for a general anisotropic uniaxial diamagnetic and dielectric medium is analyzed. We discuss light wave propagation in this moving uniaxial medium, for which the corresponding optical metrics are identified explicitly. A Lagragian for the coupled system of a nematic liquid crystal and the electromagnetic field is constructed, from which a complete set of equations of motion for the system is derived. The canonical energy-momentum and spin tensors are systematically obtained. We compare our results with those within the nonrelativistic models. As an application of our general formalism, we discuss the so-called Abraham-Minkowski controversy on the momentum of light in a medium.

I. INTRODUCTION

Liquid crystals provide an interesting example of a subject where the fundamental and applied sciences are deeply related. After their first experimental discovery more than 120 years ago, great number of substances (natural and synthesized) with the properties of liquid crystals are known, which have many important practical applications for modern technology. Good overviews and introduction to this subject can be found, for example, in Refs. [1–8]. In our study, we deal with nematic liquid crystals (with a possible generalization to cholesteric crystals) which fall into a particular class of media with microstructure. In classical continuum mechanics, a material medium consists of structureless points. In the early 20th century, the Cosserat brothers [9] proposed a generalization of this simple picture, in which the material body or fluid is formed by particles whose microscopic properties contribute to the macroscopic dynamics of the medium. These more complex continuous mechanical models are known under different names, such as the theories of multipolar, micromorphic, or oriented media [10–12]. An important particular case of continua with microstructure is represented by the spinning fluids [13–15].

As a medium with anisotropic electromagnetic (optical) properties, a nematic liquid crystal is another particular case of a medium with microstructure. Just like the spinning fluid, which is characterized by elements with an “internal” degree of freedom associated with spin, the liquid crystal is a medium of “stretched” particles whose orientational motion is described by an additional hydrodynamic variable. Mathematically, this additional degree of freedom is a unit vector field \( \mathbf{n} = \mathbf{n}(\mathbf{x},t) \), \( \mathbf{n}^2 = 1 \), which is called director. The director is a microscopic variable that is assigned to every material point of the medium. For the cholesteric liquid crystals, in addition, the chirality (handedness) property is assigned to the material points.

We construct here a complete relativistic Lagrangian theory of nematic liquid crystals interacting with the electromagnetic field. The nonrelativistic variational models were developed previously in Refs. [16,17]; see also [7]. This variational approach is convenient for the study of the full nonlinear dynamics of a liquid crystal, namely the equations of motion and the conservation laws. Relativistic fluid models are working tools in various fields of research such as high-energy plasma astrophysics and nuclear physics (where nonideal fluids are extremely successfully applied to the description of heavy ion reactions) [18,19]. Also in cosmology, hydrodynamical descriptions of matter are standard both for the early and for the later stages of the evolution of the universe. Our derivations make use of the earlier studies in which the relativistic Lagrangian theories were developed for ideal fluids without [20–22] and with microstructure [23]. Of special interest are the models [24,25] of relativistic spinning fluids. Since we use the Lagrangian formalism it is nontrivial to take into account dissipative effects. In this work we neglect dissipation in the motion of the relativistic liquid crystal and therefore our model has to be understood as a first step towards a more realistic theory. On the other hand, the description of light propagation in this medium is not affected by the inclusion of viscosity. Additionally, even in the case in which the medium is a “rigid” nondissipative anisotropic (birefringent) crystal, a model in terms of a “liquid” (i.e., a fluid) is needed to consistently describe its response to the electromagnetic field, since the
The Minkowski metric is defined as 

\[ g_{\alpha\beta} = \begin{pmatrix} 1 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 \\
0 & 0 & -1 & 0 \\
0 & 0 & 0 & -1 \end{pmatrix} \]

with the Latin indices from the beginning of the alphabet \( a, b, c, \ldots \) and the indices from the middle of the Latin alphabet \( i, j, k, \ldots \).

The analog between cosmological defects and defects in liquid crystals to curved space-times is fairly straightforward. A generalization of the relativistic Lagrangian model of liquid crystals can be used to decompose \( \hat{\varepsilon}^{ab} \) and \( \hat{\mu}^{-1}_{ab} \) in terms of its eigenvectors. By choosing these vectors as \( \mathbf{n}_1, \mathbf{n}_2, \) and \( \mathbf{n}_3, \) with two eigenvalues equal and one different, we have 

\[
\varepsilon = \varepsilon_1 n^a_1 n^b_1 + \varepsilon_\perp (n^a_1 n^b_2 + n^a_2 n^b_1),
\]

\[
\mu = \mu_1^{-1} n^a_1 n^b_1 + \mu_\perp^{-1} (n^a_1 n^b_2 + n^a_2 n^b_1).
\]

The dielectric and magnetic anisotropies are defined, respectively, by

\[ \Delta \varepsilon := \varepsilon_1 - \varepsilon_\perp, \]

\[ \Delta \mu := \mu_1^{-1} - \mu_\perp^{-1}. \]

The latter quantity should not be misunderstood as the inverse of the difference \( \mu_1 - \mu_\perp \), that is, \( \Delta \mu^{-1} \neq (\Delta \mu)^{-1} \). Strictly speaking, one should write (2.11) as \( \Delta (\mu^{-1}) \), but we omit the parentheses to simplify the formulas.

II. CONSTITUTIVE RELATIONS OF A LIQUID CRYSTAL AT REST

In Maxwell’s theory [37] the electromagnetic field is described by the electromagnetic field strength \( F_{ij} = (E_i, B_j) \) and the electromagnetic excitation \( \mathbf{H}^J = (\mathbf{D}, \mathbf{H}) \). Additionally, in order to obtain a predictive theory, one needs to specify the constitutive relations \( \mathbf{H}^J = H^J(F_{ij}) \) for the specific medium under consideration.

A liquid crystal is a medium with uniaxial anisotropic properties. The constitutive relations for a medium with electric and magnetic properties of this kind can be expressed, when the medium is at rest, by

\[ D^a = \varepsilon_0 \varepsilon^{ab} E_b, \]

\[ H_a = \mu_0^{-1} \mu_{ab}^{-1} B^b. \]

Here \( \varepsilon^{ab} \) is the relative permittivity tensor and \( \mu_{ab}^{-1} \) is the inverse of the relative permeability tensor \( \mu_{ab}^{-1} \). The fact that all quantities are considered in the frame where the medium is at rest is indicated with the symbol \( \circ \).

Alternatively to (2.1) and (2.2), it is also useful to write the constitutive relations in terms of the polarization and magnetization fields:

\[ P^a = \varepsilon_0 (\varepsilon^{ab} - \delta^{ab}) E_b, \]

\[ M_a = \mu_0^{-1} (\delta_{ab} - \mu_{ab}^{-1}) B^b. \]

In the case when the medium has the same optical axis \( \mathbf{n} \) for the electric and magnetic anisotropy, it is convenient to decompose \( \varepsilon^{ab} \) and \( \mu_{ab}^{-1} \) in terms of its eigenvectors. By choosing these vectors as \( \mathbf{n}_1, \mathbf{n}_2, \) and \( \mathbf{n}_3, \) with two eigenvalues equal and one different, we have

\[ \varepsilon = \varepsilon_1 n^a_1 n^b_1 + \varepsilon_\perp (n^a_1 n^b_2 + n^a_2 n^b_1), \]

\[ \mu = \mu_1^{-1} n^a_1 n^b_1 + \mu_\perp^{-1} (n^a_1 n^b_2 + n^a_2 n^b_1). \]

The dielectric and magnetic anisotropies are defined, respectively, by

\[ \Delta \varepsilon := \varepsilon_1 - \varepsilon_\perp, \]

\[ \Delta \mu := \mu_1^{-1} - \mu_\perp^{-1}. \]

The nonrelativistic liquid crystal theory is a well established subject; see, for instance, [1,3,8,38–44]. Nevertheless, the Lagrangian approach for the study of the dynamics of this medium with microstructure was developed only recently in Refs. [16,17] (although the variational methods were used in Ref. [7] for the analysis of the equilibrium problems for the liquid crystals).
According to [16,17], the nonrelativistic kinetic energy density of a liquid crystal reads
\[ \mathcal{K} := \rho_m \frac{v^2}{2} + \rho_m \mathcal{J} \omega^2. \] (3.1)
Here \( \rho_m(x,t) \) is the mass density of the liquid crystal, \( v(x,t) \) its velocity field, \( \mathcal{J} \) the geometric moment of inertia of a fluid element (dimensionless), and \( \omega \) the angular velocity of the director, which is defined as
\[ \omega := n \times \dot{n}, \] (3.2)
with \( n(x,t) \) the director field of the liquid crystal and
\[ \dot{n} := \frac{\partial n}{\partial t} + (v \cdot \nabla)n \] (3.3)
the convective derivative of the director.

The potential energy density is represented by the free energy \( \mathcal{F} \), which is usually taken as the thermodynamic potential of the theory of liquid crystals. Following [1,8,16,17], we express the free energy as
\[ \mathcal{F} = \mathcal{F}_0 + \mathcal{F}_d + \mathcal{F}_a + \mathcal{F}_m, \] (3.4)
where \( \mathcal{F}_d = \mathcal{F}_d(\rho_m,T) \) is the internal free energy which describes the hydrodynamic portion of \( \mathcal{F} \) and depends on the density \( \rho_m \) and the temperature \( T \). The pressure in the medium is introduced as \( p := \rho_m(\partial \mathcal{F}_0/\partial \rho_m) \). The internal dynamics of the director field is described by the Frank deformation potential \( \mathcal{F}_d \) which is defined in Ref. [1], for the simpler liquid crystal with group symmetry (\( \infty/mm \)), by
\[ \mathcal{F}_d = \frac{1}{2} K_1 (\nabla \cdot n)^2 + \frac{1}{2} K_2 (n \cdot \nabla \times n)^2 + \frac{1}{2} K_3 (n \times \nabla \times n)^2. \] (3.5)
The three parameters \( K_1, K_2, \) and \( K_3 \) are known as Frank’s elastic constants (elastic moduli), which are all independent from each other and also positive. One usually calls \( K_1 \) splay, \( K_2 \) twist, and \( K_3 \) bend constants. The so-called saddle-splay boundary term is omitted, since it is a total derivative that does not contribute to the equations of motion. For a typical nematic crystal, one has \( K_1 = 2.3 \times 10^{-12} \) N, \( K_2 = 1.5 \times 10^{-12} \) N, \( K_3 = 4.8 \times 10^{-12} \) N (see [1,7]).

The cholesteric liquid crystals are characterized by an additional modulus \( K_0 \) and a constitutive constant \( \tau \), related to the chirality of the medium. As a result, the Frank potential (3.5) is modified to
\[ \mathcal{F}_d = K_0 \tau (n \cdot \nabla \times n + \tau) + \frac{1}{2} K_1 (\nabla \cdot n)^2 + \frac{1}{2} K_2 (n \cdot \nabla \times n + \tau)^2 + \frac{1}{2} K_3 (n \times \nabla \times n)^2. \] (3.6)
We restrict ourselves to the case of the nematic crystals with \( \tau = 0 \), although the generalization to the cholesteric crystals is straightforward.

The interaction free energy of the liquid crystal with an electric field \( E \) is represented by \( \mathcal{F}_a \). Generally, controlled in the field \( E \), the electric free energy of the system [45] reads \( \mathcal{F}_a = -\int P \cdot dE \). Using (2.3) and the expression for the permittivity tensor in the comoving frame (2.8), we explicitly obtain
\[ \mathcal{F}_a = \frac{1}{2} \varepsilon_0 (\varepsilon_\perp - 1) E^2 - \frac{1}{2} \varepsilon_0 \Delta \varepsilon (n \cdot E)^2. \] (3.7)
Analogously [3,46], we have \( \mathcal{F}_m = -\int M \cdot dB \) for the magnetic free energy controlled in the field \( B \), which yields
\[ \mathcal{F}_m = -\frac{1}{2 \mu_0} (1 - \mu_\perp) B^2 + \frac{1}{2 \mu_0} \Delta \mu_\perp (n \cdot B)^2. \] (3.8)

Then, the nonrelativistic Lagrangian of the nematic liquid crystal is constructed as the difference \( \mathcal{L}_{nr} = \mathcal{K} - \mathcal{F} \) of the kinetic energy density \( \mathcal{K} \) and the “potential” free energy density \( \mathcal{F} \). Accordingly, we have
\[ \mathcal{L}_{nr} = \rho_m \frac{v^2}{2} + \rho_m \mathcal{J} \omega^2 - \mathcal{F}_0(\rho_m,T) - \frac{1}{2} K_1 (\partial_\mu n^\mu)^2 - \frac{1}{2} K_2 (\epsilon^{abc} n_a \partial_\mu n_c)^2 - \frac{1}{2} K_3 (\epsilon_{abc} n_a \epsilon^{cde} \partial_\mu n_e)^2 + \frac{1}{2} \varepsilon_0 \varepsilon_\perp E^2 + \frac{1}{2} \varepsilon_0 \Delta \varepsilon (n \cdot E)^2 - \frac{1}{2 \mu_0} \mu_\perp B^2 - \frac{1}{2 \mu_0} \Delta \mu_\perp (n \cdot B)^2, \] (3.9)
where we added the energy density of the pure electromagnetic field \( \varepsilon_0 E^2/2 - B^2/2 \mu_0 \). This is necessary to describe the electromagnetic field as a dynamical part of the system and to guarantee the correct limit of the energy density in free space.

The total nonrelativistic liquid crystal Lagrangian (3.9) can be conveniently recast into the sum of the matter part \( \mathcal{L}_{nr}^m(\rho_m,T,v^\mu,n^a,\partial_\mu n^a) \) and the electromagnetic part \( \mathcal{L}_{nm}^e(n^a,E_a,B^a) \),
\[ \mathcal{L}_{nr} = \mathcal{L}_{nr}^m + \mathcal{L}_{nr}^e, \] (3.10)
where
\[ \mathcal{L}_{nr}^m = \rho_m \frac{v^2}{2} + \rho_m \mathcal{J} \omega^2 - \mathcal{F}_0(\rho_m,T) - \frac{1}{2} K_1 (\partial_\mu n^\mu)^2 - \frac{1}{2} K_2 (\epsilon^{abc} n_a \partial_\mu n_c)^2 - \frac{1}{2} K_3 (\epsilon_{abc} n_a \epsilon^{cde} \partial_\mu n_e)^2, \] (3.11)
\[ \mathcal{L}_{nm}^e = \frac{1}{2} \varepsilon_0 \varepsilon_\perp E^2 + \frac{1}{2} \varepsilon_0 \Delta \varepsilon (n \cdot E)^2 - \frac{1}{2 \mu_0} \mu_\perp B^2 - \frac{1}{2 \mu_0} \Delta \mu_\perp (n \cdot B)^2. \] (3.12)

The nonrelativistic variational theory based on the Lagrangian (3.9) was developed in Refs. [16,17]. It used the Lagrange approach and was formulated in terms of \( (E,H) \) instead of the fields \( (E,B) \). Dynamics of the total system is determined by the action integral \( I_{nr} = \int dt d^3x \mathcal{L}_{nr} \).

IV. RELATIVISTIC LIQUID CRYSTAL LAGRANGIAN

The formal theory of liquid crystals has been studied only in the nonrelativistic domain, as can be seen in Refs. [1–8,16,17,38–41]. Here we develop a truly relativistic model for these systems, generalizing the nonrelativistic three-dimensional objects and operations to the corresponding four-dimensional notions. In contrast to [16,17], we work in the Euler approach which is more convenient for field-theoretical applications.

First, we notice that the 3-velocity field of the liquid crystal \( v \) is proportional to the spatial part of the 4-velocity \( u^\mu = (\gamma,\gamma v) \), which by definition always satisfies the condition
\[ u^\mu u_\mu = c^2 > 0. \] (4.1)
Thus, $u^i$ is a timelike 4-vector field. Here $\gamma = 1/\sqrt{1 - v^2/c^2}$ is the usual Lorentz factor. Analogously, we can define the director 4-vector $N^i$ as the relativistic covariant generalization of the director $n^i$. When the medium is at rest, $N^i$ should reduce to $n^i$; that is,

$$\hat{N}^i = (0, n).$$

We now recall that $n$, by definition, has a unit length. This together with (4.2) imposes the scalar condition

$$N^i N_i = -1 < 0,$$

which should be fulfilled in all reference frames. In other words, $N^i$ is a spacelike 4-vector. In the rest frame, $\hat{u}^i = (1, 0)$, and together with (4.2), we have $\hat{u}^i N_i = 0$. Since this is a scalar condition, it must be valid in all reference frames as well:

$$N^i u_i = 0.$$  

(4.4)

In addition, it is necessary to define a relativistic generalization of the three-dimensional Levi-Civita symbol in order to consistently express the “cross products” in Eq. (3.9). Let us introduce

$$\epsilon_{ijk} := \eta_{ijk} \frac{u^i}{c},$$

with the four-dimensional Levi-Civita tensor defined such that $\eta_{0123} := \sqrt{-g} = c$ and thus in the rest frame its spatial components reduce to the usual three-dimensional Levi-Civita symbol $\tilde{\epsilon}_{abc}$, with $\tilde{\epsilon}^{123} = 1$. Using this object, we immediately define the angular 4-velocity of the director by

$$\omega^i := \epsilon^{ijk} N_j N_k,$$

where the convective “time” derivative is naturally

$$\dot{N}^i = u^i \partial_j N^j.$$  

(4.7)

The relativistic variational theory of an ideal fluid with structureless material elements is a well developed subject [20–23,26]. The generalization to the ideal fluid with classical spin (modeled after the Dirac particles) was done in Refs. [24,25]; see also the references therein.

A liquid crystal medium represents another example of a fluid with microstructure, represented by the director field attached to each element of the fluid. Here we develop a relativistic variational model for this system by combining the variational model described in Ref. [26] (for the kinetic translation energy and the internal energy), with the four-dimensional generalization of the liquid crystal elastic terms in Eq. (3.11):

$$L^m = -\nu u^i \partial_i \Lambda_1 + \Lambda_2 u^i \partial_i s + \Lambda_3 u^i \partial_i X - \frac{1}{2} J \nu \omega^i \dot{\omega}_i$$

$$- \rho (v, s) - \frac{1}{2} K_1 (\partial_i N^i)^2 - \frac{1}{2} K_2 (\epsilon_{ijk} N_j \partial_i N_k)^2$$

$$+ \frac{1}{2} K_3 (\epsilon_{ijk} N_j \epsilon^{klm} \partial_k N_m)^2 + \Lambda_0 (u^i u_i - c^2)^2$$

$$+ \Lambda_4 (N_i^2 N_i + 1) + \Lambda_5 u^i N_i.$$  

(4.8)

Here $v$ is the particle number density of the liquid crystal, $J$ is the moment of inertia of one element [related to $\mathcal{J}$ in Eq. (3.1)] by means of $\mathcal{J} \rho_m = J v |v|$, $\rho (v, s)$ is the internal energy density of the relativistic fluid, $s$ is the entropy density, $X$ is the identity (Lin) coordinate, and $\Lambda_i$, with $I = 0, \ldots, 5$ are Lagrange multipliers. By imposing these $\Lambda_i$’s we ensure the fulfillment of the conditions (4.1), (4.3), and (4.4) throughout all the dynamics of the nematic liquid crystal, in addition to the particle number continuity equation,

$$\partial_i (\nu u^i) = 0,$$  

(4.9)

and the conservation of entropy and identity of particles along each streamline of the fluid:

$$u^i \partial_i s = 0,$$  

(4.10)

$$u^i \partial_i X = 0.$$  

(4.11)

A different sign of the $K_2$ term in Eq. (4.8), as compared to (3.11), is explained by the fact that the 4-vector $\epsilon_{ijk} N^j \epsilon^{klm} \partial_k N_m$ is spacelike, hence the square of its 4-length is negative. Notice that, as is usual in relativistic fluid models, we choose $s$ and $\nu$ as the independent thermodynamic quantities, instead of $T$ and $\rho_m$ as in the nonrelativistic case. This choice is conventional, since all the other thermodynamic quantities can be derived from them.

The dynamics of the relativistic system is governed by the action $I = (1/c) \int \sqrt{-g} d^4 x \mathcal{L}^m$. One may wonder how the nonrelativistic translational Lagrangian can be recovered from the relativistic Lagrangian. As a first step, we represent the internal energy density as the sum $\rho = \rho_m c^2 + \mathcal{F}$ of the “rest-mass” density and the hydrodynamic energy density. Consider now an arbitrary volume element which reads $\sqrt{-g} d^4 x = c dV_0 d\tau$ in the comoving reference frame with the 3-volume $dV_0$ and the proper time $\tau$. The next step is to notice that the rest mass of a fluid’s element $dm_0 = \rho_0 dV_0$ is the same in all frames and the invariant volume element $dV_0 = dV/d\tau$ [with $d\tau = \sqrt{1 - v^2/c^2} dt \approx (1 - v^2/2c^2) dt$] in the reference frame where the fluid’s element $dV$ has velocity $v$. As a result, in the nonrelativistic limit we indeed recover the translational part of the Lagrangian: $(1/c) \int \sqrt{-g} d^4 x (-\rho) \approx \int dt dV (\rho_m v^2/2 - \mathcal{F})$. A more detailed discussion can be found in Ref. [47], for example.

V. LAGRANGIAN FOR THE ELECTROMAGNETIC FIELD INTERACTING WITH THE LIQUID CRYSTAL MEDIUM

In order to describe the interaction of the electromagnetic field with matter in an explicitly covariant manner, we make use of the standard electromagnetic Lagrangian given by

$$\mathcal{L}^e = -\frac{1}{4} H^{ij} F_{ij}.$$  

(5.1)

It yields the macroscopic Maxwell equations as Euler-Lagrangian equations without sources (we assume that the fluid elements are not electrically charged):

$$\partial_j H^{ij} = 0.$$  

(5.2)

Here the electromagnetic strength tensor $F_{ij}$ is expressed in terms of the electromagnetic 4-potential $\mathcal{A}_i$, as usual by $F_{ij} := \partial_i \mathcal{A}_j - \partial_j \mathcal{A}_i$, and $H^{ij}$ is the covariant electromagnetic excitation tensor [26,37].

The constitutive relations for any linear, nondissipative, and nondispersive medium can be expressed in general covariant form by

$$H^{ij} = \frac{1}{2} \epsilon^{ijkl} F_{kl},$$  

(5.3)
where \( \chi^{ijkl} \) is the so-called constitutive tensor with the symmetries
\[
\chi^{ijkl} = - \chi^{jikl} = - \chi^{ijlk} = \chi^{klij}.
\] (5.4)
Therefore, it has 21 independent components, in general. If we insert (5.3) into (5.1), we obtain
\[
L^{em} = - \frac{1}{8} \chi^{ijkl} F_{ij} F_{kl}.
\] (5.5)
Historically, the general constitutive relation (5.3) was first formulated by Bateman [48], Tamm [49–51], and later in the modern notation by Post [52].

As we commented in Sec. II, the nematic liquid crystal is an example of a uniaxial dielectric and diamagnetic anisotropic medium and therefore we need to find an explicit covariant expression for the constitutive tensor \( \chi^{ijkl} \) for a medium of this kind.

A. Constitutive tensor in the comoving frame

The components of the covariant constitutive relation (5.3) must reproduce the expressions (2.8) and (2.9), in the rest frame of the medium. Therefore, given \( \gamma^{ab} \) and \( \mu^{-1} \) in terms of the director \( n \) and the eigenvalues \( \varepsilon_\perp, \varepsilon_\parallel, \mu_\perp \), and \( \mu_\parallel \), the nonvanishing components of \( \gamma^{ijkl} \) must explicitly read
\[
\gamma^{abcd} = \epsilon^{abef} \epsilon^{gdef} \gamma^{ijkl} = \mu_\perp^{-1} \left( \delta^{ac} \delta^{bd} - \delta^{ad} \delta^{bc} \right) - \Delta \mu_\perp^{-1} \left( \delta^{ac} n^d n^d - \delta^{ad} n^b n^c \right) + \delta^{bd} n^b n^c - \delta^{bc} n^b n^d.
\] (5.6)

It is worthwhile to notice that this constitutive tensor characterizes all nonmagnetoelectric anisotropic media with dielectric and diamagnetic uniaxial symmetries (described by \( \chi^{ijkl} \) equations (5.2) in a source-free and homogeneous medium:

\[
\gamma^{ij} k_i k_j = n^2 k^2_0 - \alpha_m k^2 + (\alpha_m - 1)(n \cdot k)^2,
\] (5.12)

with the refractive index
\[
n^2 := \mu_\perp \varepsilon_\perp.
\] (5.13)

The parameters \( \alpha_e \) and \( \alpha_m \) quantify the proportion of dielectric and diamagnetic uniaxial anisotropy in the medium and read
\[
\alpha_e := \frac{\varepsilon_\perp}{\varepsilon_\parallel}, \quad \alpha_m := \frac{\mu_\perp}{\mu_\parallel}.
\] (5.14)

One of the reduced quadratic Fresnel dispersion relations, \( \gamma^{ij} k_i k_j = 0 \), implies that if \( k \) is parallel to \( n \), then \( n^2 k^2_0 - k^2 = 0 \), which means that in this case light propagates with the expected effective refraction index of the ordinary ray: \( n \). On the other hand, if \( k \) is orthogonal to \( n \) then the dispersion relation reduces to \( n^2 k^2_0 - \alpha_m k^2 = 0 \). This means that light propagates with an effective refraction index \( n_e \), given by \( n^2_e = n^2 / \alpha_e = (\varepsilon_\parallel / \mu_\parallel) \). We may call this the dielectric extraordinary ray. Similarly, the second Fresnel dispersion relation, \( \gamma^{ij} k_i k_j = 0 \), leads to a normal ordinary ray refraction index \( n \) for waves with wave vector \( k \) parallel to the optical axis \( n \). For \( k \perp n \), it implies that light propagates with a refraction index \( n_m \), with \( n^2_m = n^2 / \alpha_m = \varepsilon_\perp / \mu_\perp \), corresponding to the diamagnetic extraordinary ray.

B. Dispersion relations and factorization of the Fresnel equation

If we look for wave solutions to the macroscopic Maxwell’s equations (5.2) in a source-free and homogeneous medium (described by \( \chi^{ijkl} \)), then the general dispersion relation is determined in covariant form by the fourth order Fresnel equation for the 4-wave covector \( k \):
\[
G^{ijkl} k_i k_j k_k k_l = 0.
\] (5.8)
Here \( G^{ijkl} \) is the Tamm-Rubilar tensor [53], given by
\[
G^{ijkl} := \frac{1}{4c^2} \eta_{mnpq} \eta_{rstu} \chi^{mns} \chi^{pru} \chi^{qtr} \chi^{stu}.
\] (5.9)

We can use the nonvanishing components of the constitutive tensor (5.6) and (5.7) in Eqs. (5.9) and (5.8) and thereby verify the factorization of the fourth order Fresnel wave surface into a product of two light cones, determined by two optical metrics in the rest frame of the medium:
\[
\gamma^{ijkl} k_i k_j k_k k_l = (\gamma^{ij} k_i k_j) (\gamma^{kl} k_k k_l) = 0.
\] (5.10)
Here the light cones read explicitly
\[
\gamma^{ij} k_i k_j = n^2 k^2_0 - \alpha_e k^2 + (\alpha_e - 1)(n \cdot k)^2,
\] (5.11)
terms of the two optical metrics (5.15) and (5.16), by

\[ \chi^{ijkl} = \frac{1}{\mu_0 \mu_\perp} \left( \gamma^{ij}_e \gamma^{kl}_e - \gamma^{il}_e \gamma^{jk}_e \right) \\
+ \frac{1}{(\alpha_m - \alpha_e) \mu_0 \mu_\perp} (\Delta \gamma^{ik} \Delta \gamma^{jl} - \Delta \gamma^{il} \Delta \gamma^{jk}), \]

(5.18)

where \( \Delta \gamma^{ij} \) is the difference of the optical metrics,

\[ \Delta \gamma^{ij} := \gamma^{ij}_e - \gamma^{ij}_m. \]

\[ \Delta \gamma^{ij} = (\alpha_e - \alpha_m) \pi^{ij}. \]

\[ \Delta \gamma^{ij} = (\alpha_e - \alpha_m) \pi^{ij}. \]

\[ \Delta \gamma^{ij} = (\alpha_e - \alpha_m) \pi^{ij}. \]

\[ \Delta \gamma^{ij} = (\alpha_e - \alpha_m) \pi^{ij}. \]

D. The projector \( \pi^{ij} \) and the isotropic limit

Let us define the projector \( \pi^{ij} \) to the two-dimensional space orthogonal to \( N^i \) and \( u^j \),

\[ \pi^{ij} := g^{ij} - \frac{1}{c^2} u^i u^j + N^i N^j. \]

(5.20)

It obviously has the properties \( \pi^i j \pi^j k = \pi^i k \) and \( \det(\pi^{ij}) = 0 \).

With this object we can write the optical metrics in a more compact form:

\[ \gamma^{ij}_e = \gamma^{ij} + (\alpha_e - 1) \pi^{ij}, \]

(5.21)

\[ \gamma^{ij}_m = \gamma^{ij} + (\alpha_m - 1) \pi^{ij}, \]

(5.22)

where \( \gamma^{ij} \) is the usual optical Gordon metric of an isotropic medium [26,55],

\[ \gamma^{ij} = g^{ij} + \left( \frac{n^2 - 1}{c^2} \right) u^i u^j. \]

(5.23)

Also the difference of optical metrics Ref. (5.19) can be expressed in terms of \( \pi^{ij} \),

\[ \Delta \gamma^{ij} = (\alpha_e - \alpha_m) \pi^{ij}. \]

(5.24)

Therefore, the constitutive tensor in Ref. (5.18) can be recast into the form

\[ \chi^{ijkl} = \frac{1}{\mu_0 \mu_\perp} \left[ \frac{1}{\mu_0} \left( \gamma^{ik}_e \gamma^{jl}_e - \gamma^{ij}_e \gamma^{kl}_e \right) \\
- (\alpha_e - \alpha_m) (\pi^{ik} \pi^{jl} - \pi^{il} \pi^{jk}) \right]. \]

(5.25)

From (5.25), we can easily check that our \( \chi^{ijkl} \) reduces to the well-known expression for the isotropic case in terms of the Gordon metric (5.23), when

\[ \varepsilon_\parallel \rightarrow \varepsilon_\perp = \varepsilon \leftrightarrow \alpha_e \rightarrow 1, \]

(5.26)

\[ \mu_\parallel \rightarrow \mu_\perp = \mu \leftrightarrow \alpha_m \rightarrow 1. \]

(5.27)

Then both optical metrics in Eqs. (5.21) and (5.22) become the single Gordon metric, and the constitutive tensor metric, by inserting (5.34) and (5.35) into (5.33), we can separate the contributions of the electromagnetic Lagrangian in “isotropic” and “anisotropic” parts, that is,

\[ \mathcal{L}^{\text{em}} = \mathcal{L}^{\text{iso}} + \mathcal{L}^{\text{ani}}, \]

(5.36)

with

\[ \mathcal{L}^{\text{iso}} = -\frac{1}{2} \left\{ \varepsilon_0 \varepsilon_\parallel \mathcal{E}^i \mathcal{E}_i - \mu_0 \mu_\perp \mathcal{B}^i \mathcal{B}_i \right\}, \]

(5.37)

\[ \mathcal{L}^{\text{ani}} = \frac{1}{2} \left\{ \varepsilon_0 \Delta \varepsilon (\mathcal{E}_i N^i)^2 - \mu_0 \mu_\perp \Delta \mu^{-1} (\mathcal{B}_i N^i)^2 \right\}. \]

(5.38)

As we see, the structure of (5.36), (5.37), and (5.38) follows exactly the structure of the nonrelativistic Lagrangian (3.12). By inserting (5.31) and (5.32) into (5.37), we can write the

excitation \( H^{ij} \):

\[ H^{ij} = \frac{1}{\mu_0} \left( \mu_\perp^{-1} + \Delta \mu^{-1} \right) F^{ij} + \frac{2}{\mu_0} \Delta \mu^{-1} F^{ik} N^k N^n \]

\[ + \frac{2}{\mu_0 c^2 (\varepsilon_\perp - \mu_\perp^{-1} - \Delta \mu^{-1})} \right( (\mathcal{E} \mathcal{B})^i N^i)^2 \]

\[ - \frac{2}{\mu_0 c^2 (\Delta \varepsilon + \Delta \mu^{-1})} (\mathcal{E} \mathcal{B})^i N^i (\mathcal{E} \mathcal{B})^i N^i. \]

(5.29)

From here on, we assume that the permittivity and permeability can be functions of the particle density, \( \mu_\perp = \mu_\perp(v), \varepsilon_\perp = \varepsilon_\perp(v), \) and \( \Delta \mu^{-1} = \Delta \mu^{-1}(v), \) in general. Then, from (5.1) and (5.29), it is straightforward to compute an explicit expression for the electromagnetic Lagrangian \( \mathcal{L}^{\text{em}} = \mathcal{L}^{\text{em}(v,u^i,N^i,F_{ij})} \), which reads

\[ \mathcal{L}^{\text{em}} = -\frac{1}{4 \mu_0} \left( \mu_\perp^{-1} + \Delta \mu^{-1} \right) F^{ij} F_{ij} - \frac{1}{2 \mu_0} \Delta \mu^{-1} (F_{ik} N^k)^2 \]

\[ - \frac{1}{2 \mu_0 c^2 (\varepsilon_\perp - \mu_\perp^{-1} - \Delta \mu^{-1})} (F_{ik} N^k)^2 \]

\[ + \frac{1}{2 \mu_0 c^2 (\Delta \varepsilon + \Delta \mu^{-1})} (F_{ik} N^k)^2. \]

(5.30)

For completeness, we also give an alternative derivation of (5.30) based directly on the nonrelativistic Lagrangian (3.12).

In the four-dimensional relativistic framework, the electric \( E \) and magnetic \( B \) fields are substituted with the 4-vectors of electric field \( \mathcal{E}_i \) and magnetic field \( \mathcal{B}^i \), defined as

\[ \mathcal{E}_i := F_{ij} u^j, \]

(5.31)

\[ \mathcal{B}^i := \frac{1}{c} \eta^{ijkl} F_{jk} u^l. \]

(5.32)

Then the electromagnetic Lagrangian (5.1) can be alternatively written in a “three-dimensional-like” form,

\[ \mathcal{L}^{\text{em}} = \frac{1}{2} \left( \varepsilon_0 (\mathcal{E} \mathcal{E})^i - \mu_0^{-1} \mu_\perp^{-1} (\mathcal{B} \mathcal{B})^i \right), \]

(5.33)

where \( \mathcal{E}^{ij} \) is the 4-permittivity tensor and \( \mu_\perp^{-1} \) the inverse of the 4-permeability tensor, given by

\[ \varepsilon^{ij} := -\varepsilon_\perp g^{ij} + \Delta \varepsilon N^i N^j, \]

(5.34)

\[ \mu_\perp^{-1} := -\mu_\perp^{-1} g^{ij} + \Delta \mu^{-1} N^i N^j. \]

(5.35)
isotropic electromagnetic Lagrangian $\mathcal{L}^{\text{iso}}$ in terms of $F^{ij}$:

$$\mathcal{L}^{\text{iso}} = -\frac{1}{4\mu_0\mu_\perp} g^{ik} g^{jl} F_{ij} F_{kl} - (n^2 - 1) \frac{1}{2\mu_0\mu_\perp} c^2 g^{ik} u^l u^j F_{ij} F_{kl}$$

(5.39)

$$= -\frac{1}{4\mu_0\mu_\perp} \gamma^{ij} \gamma^{kl} F_{ij} F_{kl}$$

(5.40)

$$= -\frac{1}{8} \chi^{ijkl}_{\text{iso}} F_{ij} F_{kl},$$

(5.41)

where $\chi^{ijkl}_{\text{iso}}$ is the constitutive tensor for the isotropic case given in (5.28) and written in terms of the Gordon metric (5.23). In this case $n^2 = \varepsilon_{\perp \mu_\perp}$ as expected.

Now we do the same for the anisotropic part of the electromagnetic Lagrangian (5.38). First, using the definitions (5.31) and (5.32), we explicitly have the following expressions:

$$\mathcal{L}^{\text{ani}} = -\frac{1}{4\mu_0} \Delta \mu^{-1} g^{ik} g^{jl} F_{ij} F_{kl} - \frac{1}{2\mu_0} \Delta \mu^{-1} g^{ik} N^j N^l F_{ij} F_{kl}$$

$$+ \frac{1}{2\mu_0 c^2} \Delta \mu^{-1} g^{ik} u^l u^j F_{ij} F_{kl}$$

$$+ \frac{1}{2\mu_0 c^2} (\Delta \epsilon + \Delta \mu^{-1}) N^i N^j u^i u^j F_{ij} F_{kl}$$

(5.42)

$$= -\frac{1}{8} \chi^{ijkl}_{\text{ani}} F_{ij} F_{kl},$$

(5.43)

Then, using (5.42) and (5.43) in Eq. (5.38), we derive the explicit expression for the anisotropic Lagrangian,

$$\mathcal{L} = -\frac{1}{4\mu_0} \Delta \mu^{-1} g^{ik} g^{jl} F_{ij} F_{kl} - \frac{1}{2\mu_0} \Delta \mu^{-1} g^{ik} N^j N^l F_{ij} F_{kl}$$

$$+ \frac{1}{2\mu_0 c^2} \Delta \mu^{-1} g^{ik} u^l u^j F_{ij} F_{kl}$$

$$+ \frac{1}{2\mu_0 c^2} (\Delta \epsilon + \Delta \mu^{-1}) N^i N^j u^i u^j F_{ij} F_{kl}$$

(5.44)

$$= -\frac{1}{8} \chi^{ijkl} F_{ij} F_{kl},$$

(5.45)

with

$$\chi^{ijkl} := \mu_0^{-1} \Delta \mu^{-1} (g^{ik} g^{jl} - g^{il} g^{jk})$$

$$- \mu_0 c^2 \Delta \mu^{-1} (g^{ik} u^l u^j - g^{il} u^j u^k - g^{jk} u^i u^k)$$

$$+ \mu_0^{-1} \Delta \mu^{-1} (g^{ik} N^j N^l - g^{il} N^j N^k + g^{jk} N^i N^l)$$

$$- g^{ik} N^j N^l$$

$$- \frac{1}{\mu_0 c^2} (\Delta \epsilon + \Delta \mu^{-1}) (u^i u^j N^k N^l)$$

$$- u^i u^j N^k N^l + u^i u^j N^k N^l - u^k u^l N^i N^j),$$

(5.46)

Finally, the total constitutive tensor $\chi^{ijkl}$ in Eq. (5.17), is formed by adding (5.18) and (5.28), and is easily checked,

$$\chi^{ijkl} = \chi^{ijkl}_{\text{iso}} (\varepsilon_{\perp \mu_\perp}) + \chi^{ijkl}_{\text{ani}} (\Delta \epsilon, \Delta \mu^{-1}).$$

(5.47)

The resulting constitutive tensor is identical to (5.17).

**VI. VARIATION OF THE MATTER LAGRANGIAN**

With a well defined Lagrangian (4.8) for our relativistic model of a nematic liquid crystal, we now derive the field equations of the system. For this task, we write the matter Lagrangian $\mathcal{L}^m = \mathcal{L}^m(v, u^i, N^i, \delta_i N^i, s, X, \Lambda_i)$, $I = 0, 1, 2, 3, 4, 5$, as a sum of three terms,

$$\mathcal{L}^m = \mathcal{L}^k + \mathcal{L}^p + \mathcal{L}^\Lambda,$$

(6.1)

where

$$\mathcal{L}^k := -\frac{1}{2} J \nu \omega^j \omega_i$$

(6.2)

is the kinetic Lagrangian and

$$\mathcal{L}^p := -\rho(v, s) - \mathcal{V}$$

(6.3)

is the Lagrangian of the potential energy, with the Frank deformation potential given by

$$\mathcal{V} := \frac{1}{2} K_1 (\partial_i N^i)^2 + \frac{1}{2} K_2 (\epsilon_{ijk} N_i \partial_j N_k)^2$$

$$- \frac{1}{2} K_3 (\epsilon_{ijk} N^j \epsilon^{kli} \delta_i N_k)^2.$$ (6.4)

The Lagrangian part containing the constraints reads

$$\mathcal{L}^\Lambda := \Lambda_0 (u^j u_i - c^2) - v u^j \partial_i \Lambda_1 + \Lambda_2 u^j \partial_i s$$

$$+ \Lambda_3 u^j \partial_i X + \Lambda_4 (N^j N_i + 1) + \Lambda_5 u^j N_i.$$ (6.5)

**A. Kinetic term**

To begin with, we notice that making use of the definition (4.6), we can recast the square of the angular velocity into

$$\omega^i \omega_i = p^j N_i \dot{N}^i = N^i \dot{N}_i - \frac{1}{c^2} (u_i \dot{N}^i)^2,$$

(6.6)

where $p^j$ is the usual projector operator, perpendicular to the 4-velocity field:

$$p^j := \delta^j - \frac{1}{c^2} u^i u_j.$$

(6.7)

Therefore, the kinetic Lagrangian (6.2) depends only on $v, u^i$, and the derivatives of the director field $\partial_k N^i$. The derivative with respect to the latter reads

$$\frac{\partial \mathcal{L}^k}{\partial \dot{N}^i} = -J \nu u^k \dot{N}^i.$$ (6.8)

As a result, we find the variational derivatives of the kinetic Lagrangian with respect to its arguments

$$\frac{\delta \mathcal{L}^k}{\delta v^j} = \frac{\partial \mathcal{L}^k}{\partial v^j} = -J \nu u^k \dot{N}^i.$$ (6.9)

$$\frac{\delta \mathcal{L}^k}{\delta u^i} = \frac{\partial \mathcal{L}^k}{\partial u^i} = J v (p^j \dot{N}_i + \dot{N}_i u^j / c^2) \dot{N}_j,$$ (6.10)

$$\frac{\delta \mathcal{L}^k}{\delta N^i} = -\partial_k \left( \frac{\partial \mathcal{L}^k}{\partial \dot{N}^i} \right) + \partial_k (J v u^k \dot{N}^i).$$ (6.11)

**B. Potential term**

The potential Lagrangian (6.3) depends on $v, s, u^i, N^i$, and the derivatives of the director field $\partial_k N^i$. The derivative with respect to the latter reads

$$\frac{\partial \mathcal{L}^p}{\partial \dot{N}^i} = -\frac{\partial \mathcal{V}}{\partial \dot{N}^i}.$$ (6.12)

We straightforwardly compute the variational derivatives

$$\frac{\delta \mathcal{L}^p}{\delta v^j} = \frac{\partial \mathcal{L}^p}{\partial v^j} = -\frac{\partial \rho}{\partial v} = -p + \rho,$$ (6.13)

$$\frac{\delta \mathcal{L}^p}{\delta s} = \frac{\partial \mathcal{L}^p}{\partial s} = -\frac{\partial \rho}{\partial s} = -v T,$$ (6.14)

$$\frac{\delta \mathcal{L}^p}{\delta u^i} = \frac{\partial \mathcal{L}^p}{\partial u^i} = -\frac{\partial \mathcal{V}}{\partial u^i}.$$ (6.15)
\[
\frac{\delta L}{\delta N^i} = -\frac{\delta V}{\partial N^i} + \frac{\partial V}{\partial \delta_i N^i}.
\]  
(6.16)

In Eqs. (6.13) and (6.14) we used the thermodynamic (Gibbs) law

\[
Tds = d\left(\frac{\rho}{v}\right) + pd\left(\frac{1}{v}\right).
\]  
(6.17)

C. Constraint term

Variation with respect to the Lagrange multipliers \(\Lambda_i\) yields the complete set of constraints:

\[
u'(uu') = 0, \quad (6.19)
\]

\[
u'\delta_t s = 0, \quad (6.20)
\]

\[
u'\delta_t X = 0, \quad (6.21)
\]

\[N^i N_i = -1, \quad (6.22)
\]

\[N^i u_i = 0. \quad (6.23)
\]

Additionally, the variations of the constraint Lagrangian with respect to the field variables read

\[
\frac{\delta L^A}{\delta v} = \frac{\partial L^A}{\partial v} = -u'\delta_t \Lambda_1, \quad (6.24)
\]

\[
\frac{\delta L^A}{\delta s} = -\partial_t \left(\frac{\partial L^A}{\partial \delta_t s}\right) = -\delta_t (u' \Lambda_2), \quad (6.25)
\]

\[
\frac{\delta L^A}{\delta X} = -\partial_t \left(\frac{\partial L^A}{\partial \delta_t X}\right) = -\delta_t (u' \Lambda_3), \quad (6.26)
\]

\[
\frac{\delta L^A}{\delta u^i} = \frac{\partial L^A}{\partial u^i} = 2\Lambda_0 u_i - \nu \delta_t \Lambda_1 + \Lambda_2 \delta_t s + \Lambda_3 \delta_t X + \Lambda_5 N_i, \quad (6.27)
\]

\[
\frac{\delta L^A}{\delta N^i} = \frac{\partial L^A}{\partial N^i} = 2\Lambda_4 N_i + \Lambda_5 u_i. \quad (6.28)
\]

D. Field equations

We are now in a position to write the field equations, collecting the variations of the three terms in Eq. (6.1). We can distinguish three groups of equations. The first group describes the constraints (6.18)–(6.23). The second group concerns the variables \(s, X\) which do not enter the Lagrangian of the electromagnetic field. This yields

\[
\partial_t (u' \Lambda_2) + \nu T = 0, \quad (6.29)
\]

\[
\partial_t (u' \Lambda_3) = 0. \quad (6.30)
\]

The third group of equations is obtained from the variations with respect to the essential field variables \(v, u', \) and \(N^i\). We have explicitly

\[
\frac{\delta L^m}{\delta v} = -\frac{J}{2} \omega^2 - \frac{p + \rho}{v} - u' \delta_t \Lambda_1, \quad (6.31)
\]

\[
\frac{\delta L^m}{\delta u^i} = Jv \left(-p_j^k \partial_t N_j^k + \frac{1}{c^2} N_i^j u_j^i\right) N_j - \frac{\delta V}{\delta u^i} + 2\Lambda_0 u_i - \nu \delta_t \Lambda_1 + \Lambda_2 \delta_t s + \Lambda_3 \delta_t X + \Lambda_5 N_i, \quad (6.32)
\]

\[
\frac{\delta L^m}{\delta N^i} = \partial_t (J v u^k P_j^i \dot{N}_j) - \frac{\delta V}{\delta N^i} + 2\Lambda_4 N_i + \Lambda_5 u_i. \quad (6.33)
\]

Contracting (6.33) with \(u'\) and \(N^i\), we find the Lagrange multipliers

\[
\Lambda_5 = \frac{1}{c^2} u' \left[\frac{\delta L^m}{\delta N^i} - \partial_t (J v u^k P_j^i \dot{N}_j) + \frac{\delta V}{\delta N^i}\right]. \quad (6.34)
\]

\[
2\Lambda_4 = -N^i \left[\frac{\delta L^m}{\delta N^i} - \partial_t (J v u^k P_j^i \dot{N}_j) + \frac{\delta V}{\delta N^i}\right]. \quad (6.35)
\]

Substituting these back into (6.33), we end with the field equation for the director field:

\[
\pi^i_j \frac{\delta L^m}{\delta N^i} = \pi^i_j \left[\partial_t (J v u^k P_j^i \dot{N}_j) - \frac{\delta V}{\delta N^j}\right]. \quad (6.36)
\]

Here \(\pi^i_j\) is the projector defined in Eq. (5.20). Note that we cannot yet put equal zero the left-hand side of (6.36); it will be evaluated later from the variation of the electromagnetic part (5.30) of the total Lagrangian.

Contracting (6.32) with \(u'\), we find another Lagrange multiplier:

\[
2\Lambda_0 = \frac{1}{c^2} \left\{u' \frac{\delta L^m}{\delta u^i} - \nu \frac{\delta L^m}{\delta v} - \rho - p + Jv \left[\frac{1}{2} \omega^2 - \left(\frac{1}{c^2} \omega^2 + \frac{1}{v} \frac{\delta V}{\delta u^i}\right)^2\right] + u' \frac{\delta V}{\delta u^i}\right\}. \quad (6.37)
\]

Here again we cannot put equal zero the first two terms on the right-hand side of (6.37); they also should be inserted from the variation of (5.30).

Finally, let us notice that the material Lagrangian “on-shell” (i.e., after making use of the field equations) reads

\[
L^m = \rho + \nu \frac{\delta L^m}{\delta v} - \frac{\delta V}{\delta s} - \nu T. \quad (6.38)
\]

VII. CANONICAL NOETHER CURRENT TENSOR FOR MATTER

The general form of the canonical energy-momentum tensor for the matter part is

\[
\Sigma^{m j} := \frac{\partial L^m}{\partial \frac{\partial x^j}{\partial \xi}} \frac{\partial x^j}{\partial \xi} = \frac{\partial L^m}{\partial \partial x^j} - \frac{\partial}{\partial x^j} \frac{\partial L^m}{\partial \xi}.
\]  
(7.1)

Here \(\Psi^j\) are all dynamical variables. The matter Lagrangian (6.1) depends on the derivatives of \(N^i\) as well as on \(\Lambda_1, s, X\). The derivatives with respect to the velocity of the director field are computed from (6.8) and (6.12):

\[
\frac{\partial L^m}{\partial \delta_{\partial_t N_j^i}} = \frac{\partial L^k}{\partial \partial_t N_j^i} + \frac{\partial L^p}{\partial \partial_t N_j^i} = -J v u^k P_j^i \dot{N}_j - \frac{\delta V}{\partial \delta_t N^i}. \quad (7.2)
\]

On the other hand, from the constraint Lagrangian we find

\[
\frac{\partial L^A}{\partial \partial_t \Lambda_1} = -\nu \dot{u}', \quad \frac{\partial L^A}{\partial \partial_t s} = \Lambda_2 u', \quad \frac{\partial L^A}{\partial \partial_t X} = \Lambda_3 u'. \quad (7.3)
\]

Consequently, we have

\[
\frac{\partial L^m}{\partial \partial_t N_k^i} \partial_j N^k = -u' J v P_j^i \dot{N}_j \partial_t N^k - \frac{\delta V}{\partial \partial_t N^k} \partial_j N^k, \quad (7.4)
\]
and
\[ \frac{\partial \mathcal{L}^m}{\partial \partial_t \Lambda_1} \partial_j J_1 + \frac{\partial \mathcal{L}^m}{\partial \partial_t s} + \frac{\partial \mathcal{L}^m}{\partial \partial_t X} \partial_j X = u^i ( \nu \partial_j \Lambda_1 + \Lambda_2 \partial_j s + \Lambda_3 \partial_j X ). \] (7.5)

In order to compute the right-hand side of (7.5), we can use (6.27). The latter equation yields, with the help of (6.37) and (6.34):

\[ - \nu \partial_j \Lambda_1 + \Lambda_2 \partial_j s + \Lambda_3 \partial_j X = \left( \frac{u_j}{c^2} \right) [ \nu \frac{\partial \mathcal{L}^m}{\partial \nu} + p + \rho + \frac{4}{c^2} \nu \omega^2 ] + p^k \left[ \rho \frac{\partial \mathcal{L}^m}{\partial \rho} - \frac{\partial \mathcal{L}^m}{\partial \rho^k} + \frac{\partial \mathcal{L}^m}{\partial \rho^k} \right] - N_k \left( \frac{\partial \mathcal{L}^m}{\partial \nu} - \frac{\partial \mathcal{L}^m}{\partial \nu^k} - \frac{\partial \mathcal{L}^m}{\partial \nu^k} \right). \] (7.6)

Substituting (6.38), (7.4), (7.5), and (7.6) into (7.1), we find explicitly the canonical energy-momentum tensor of the liquid crystal:

\[ \sum_\nu = \left. \frac{F}{\partial \nu} \right|_{\mu} = - \frac{\partial \mathcal{Y}}{\partial \nu} \partial_i N^k + \delta_i^k \mathcal{Y}, \] (7.7)

the effective pressure \( p^{\text{eff}} \) reads

\[ p^{\text{eff}} := p + \nu \frac{\partial \mathcal{L}^m}{\partial \nu}, \] (7.9)

and the relativistic 4-momentum density of the fluid is

\[ \mathcal{P}_i := \frac{1}{c^2} u_i \left( \rho - \frac{1}{2} \nu \omega^2 \right) + p^k \left[ \rho \frac{\partial \mathcal{L}^m}{\partial \rho} - \frac{\partial \mathcal{L}^m}{\partial \rho^k} + \frac{\partial \mathcal{L}^m}{\partial \rho^k} \right] - N_k \left( \frac{\partial \mathcal{L}^m}{\partial \nu} - \frac{\partial \mathcal{L}^m}{\partial \nu^k} - \frac{\partial \mathcal{L}^m}{\partial \nu^k} \right). \] (7.10)

As usual, we have to compute the variational derivatives of the matter Lagrangian with respect to \( \nu, u^i, N^i \) from the electromagnetic part of the total Lagrangian (5.30).

### A. Canonical spin of liquid crystal

Denoting all the fields in the system by the symbol \( \Psi^A \), that carries a "multi-index" \( A \), with \( (\rho_j)^{(k)}_i \) as the generators of the Lorentz algebra for these fields, the spin of the system is defined by

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

Since the matter Lagrangian does not depend on the derivatives of \( u^i \), the spin of the system is straightforwardly computed with the help of (7.2):

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t N^j = - \nu u^k N^j \partial_k N^i \] (7.11)

Using the results of the Appendix, we can write down the variational derivatives for the Frank potential (6.4). They read

\[ \frac{\partial \mathcal{Y}}{\partial u^i} = \frac{-K_2}{c^2} \left( \partial_i N_j - \partial_j N_i \right) \] (7.12)

\[ \frac{\partial \mathcal{Y}}{\partial \partial_t N^j} = K_1 \left( \partial_i N^k \partial_i^j + P_i^j P_i^k \left( \partial_i^N \partial_i \right) \right), \] (7.13)

\[ \frac{\partial \mathcal{Y}}{\partial \partial_t P_i^j} = K_1 \left( \partial_i^N \partial_i^j + P_i^j P_i^k \left( \partial_i^N \partial_i \right) \right), \] (7.14)

As a consequence, the Frank stress tensor (7.8) is

\[ \sum_i = \frac{F}{\partial \nu} N_i \] (7.15)

and the spin density tensor of matter (7.12) reads

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

### B. Balance equation of the angular momentum of matter

Let us check that the angular momentum balance equation is satisfied for the open material system under consideration. This balance equation follows from the Noether theorem and it reads [26]:

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

In our system, we have two vector fields, \( u^i \) and \( N^i \), and the corresponding Lorentz generators are \( (\rho_j)^{(k)}_i \). As a result, the right-hand side of (7.18) explicitly reads

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

From (7.7) we derive the first term on the left-hand side of the balance equation (7.18):

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

Denote

\[ \Phi \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

then the field equation for the director (6.36) is recast into

\[ \sum_\nu \partial \mathcal{L}^m / \partial \partial_t \Psi^A \partial_j (\rho_j)^{(k)}_i \Psi^B \].

(7.22)
Let us consider the last term in Eq. (7.20). By making use of (7.10), we have
\[ \mathcal{P}_{[i}u_{j]} = \frac{\delta \mathcal{L}^m}{\delta u^{[i}} u_{j]} + \frac{\partial V}{\partial u^{[i}} u_{j]} + J v \dot{N}_{[i} u_{j]} u^k \dot{N}_k - N_{[i} u_{j]} u^k \Phi_k \]
\[ = \frac{\delta \mathcal{L}^m}{\delta u^{[i}} u_{j]} + \frac{\partial V}{\partial u^{[i}} u_{j]} + J v N_{[i} P^k_{j]} N_k - N_{[i} \Phi_j + N_{[i} \pi^k_{j]} \Phi_k. \]  
(7.23)

We used the definition of the projector (5.20) that yields
\[ - \frac{u_{i}^{j} u^{k}}{c^2} = \pi_{j}^{k} - \delta_{j}^{k} - N_{j} N^{k}. \]  
(7.24)

to transform the two last terms on the first line in Eq. (7.23).

In view of the field equation (7.22) the last term in Eq. (7.23) vanishes, and we find
\[ \mathcal{P}_{[i} u_{j]} = \frac{\delta \mathcal{L}^m}{\delta u^{[i}} u_{j]} + \frac{\partial V}{\partial u^{[i}} u_{j]} + J v N_{[i} P^k_{j]} N_k - N_{[i} \Phi_j \]
\[ = \frac{\delta \mathcal{L}^m}{\delta u^{[i}} u_{j]} + \frac{\delta \mathcal{L}^m}{\delta N^{[i}} N_{j]} + \frac{\partial V}{\partial u^{[i}} u_{j]} + \frac{\partial V}{\partial N^{[i}} N_{j]}
\[ + J v N_{[i} P^k_{j]} N_k + N_{[i} \Phi_j \frac{\partial}{\partial \Phi_j} v_{j]} \dot{N}_k. \]  
(7.25)

Recalling that \( \dot{N}_i = u^a \partial_a N_i \), we see that the last line reduces to the total divergence
\[ J v N_{[i} P^k_{j]} \dot{N}_k + N_{[i} \partial_a (J v u^a N_{j]} P^k_{j]} \dot{N}_k) \]
\[ = \partial_a (J v u^a N_{j]} P^k_{j]} N_k). \]  
(7.26)

After these preparations, we can find the left-hand side of the balance equation (7.18):
\[ \sum_{i[j]} + \delta_k \sum_{i} = \frac{\delta \mathcal{L}^m}{\delta \partial_a A_k} \partial_a A_k - \delta_l^k \mathcal{L}^m \]
\[ = \sum_{i} + H^{ij} \partial_a A_i. \]  
(8.1)

where \( \sum_{i} \) is the usual Minkowski tensor for the electromagnetic field in matter, given by
\[ \sum_{i} := - F_{ik} H^{jk} + \frac{1}{2} \delta_{i}^{k} F_k H^{kl}. \]  
(8.3)

Now, using the expression (5.29) in Eqs. (8.2) and (8.3), we get explicitly
\[ \sum_{i} = \frac{1}{\mu_0 (\mu_0 + \Delta \mu)} \left( - F^{ij} F_{ik} + \frac{1}{4} \delta_i^j F^{kl} F_{kl} \right) + \frac{1}{\mu_0 c^2} (\varepsilon - \mu_0 - \Delta \mu) \left[ - F^{ij} u_k u_l + \frac{1}{2} \delta_i^j (F_k u_l)^2 + u^i F_k F^{kl} u_l \right]
\[ + \frac{1}{\mu_0} \Delta \mu \left[ - F^{ij} N_k N_l + \frac{1}{2} \delta_i^j (F_k N_l)^2 + N^i F_k F^{kl} N_i \right] \]
\[ + \frac{1}{\mu_0 c^2} (\varepsilon + \Delta \mu) \left( F_{pq} N^p u^q \right). \]  
(8.4)

which is the explicit expression for the Minkowski tensor of the field inside the liquid crystal.

\textbf{A. Balance equation for the angular momentum of the electromagnetic field}

From the general definition [26], the spin density \( \tilde{S}_{ij}^k \) of the electromagnetic part of the system is given by
\[ \tilde{S}_{ij}^k = \frac{\partial \mathcal{L}^m}{\partial (\partial_a A_k)} \rho_{ij} \tilde{A}_a = H^{ij}_a A_k \neq 0. \]  
(8.5)

Now we are in position to evaluate the angular momentum balance equation for the electromagnetic part of the system, which has the same form as the one for the matter part (7.18). Taking the antisymmetric part of (8.2) and using the expression (8.5), together with the Maxwell equations without sources, \( \partial_a H^{ij} = 0 \), we see that the left-hand side of the identity for electromagnetic angular momentum is simply given by the antisymmetric part of the Minkowski tensor:
\[ \sum_{i} + \delta_k \sum_{i} = \sum_{i}. \]  
(8.6)
where
\[
\frac{M}{\Sigma_{ij}} = u_{ij} F_{i j k} \left[ \frac{1}{\mu_0 c^2} (c_\perp - \mu_\perp^{-1} - \Delta \mu_\perp^{-1}) F_{i k} u_t \right. \\
- \frac{1}{\mu_0 c^2} (\Delta \epsilon + \Delta \mu_\perp^{-1}) (F_{pq} N^p u^q) N^k \\
+ \left. N_{ij} F_{i j k} \left[ \frac{1}{\mu_0} \Delta \mu_\perp^{-1} F_{i k} N_t \right. \\
+ \left. \frac{1}{\mu_0 c^2} (\Delta \epsilon + \Delta \mu_\perp^{-1}) (F_{pq} N^p u^q) u^k \right] \right].
\] (8.7)

We see that the electromagnetic canonical energy-momentum tensor as well as the Minkowski tensor are not symmetric. However, it is not surprising that the right-hand side of (8.7) is not equal to zero since the electromagnetic Lagrangian inside matter \( \Sigma_{ij} \) describes an open system.

On the other hand, computing the variations of \( \Sigma_{ij} \) in Eq. (5.30) with respect to the material variables yields
\[
\frac{\delta \Sigma_{ij}}{\delta u^t} = \frac{1}{\mu_0 c^2} (c_\perp - \mu_\perp^{-1} - \Delta \mu_\perp^{-1}) F_{i k} F^i \delta u^k, \\
\frac{\delta \Sigma_{ij}}{\delta N^t} = \frac{1}{\mu_0} \Delta \mu_\perp^{-1} F_{i k} F^i \delta N^t, \\
\frac{\delta \Sigma_{ij}}{\delta N^i} = \frac{1}{\mu_0} \Delta \mu_\perp^{-1} F_{i k} F^k N_t. \\
\] (8.8)

Comparing (8.8) and (8.9) with (8.7), we immediately verify the correct balance equation for the electromagnetic angular momentum part of the system:
\[
\Sigma_{ij}^{\text{em}} + m S_{ij}^k = \frac{\delta \Sigma_{ij}}{\delta u^t} u_j + \frac{\delta \Sigma_{ij}}{\delta N^t} N_j. \\
\] (8.10)

This is in perfect agreement with the general Noether identity (7.18).

**IX. TOTAL CANONICAL ENERGY-MOMENTUM TENSOR**

The complete system of material medium plus electromagnetic field is described by the total Lagrangian
\[
\mathcal{L} := \mathcal{L}^m + \mathcal{L}^\text{em}.
\] (9.1)

As a result, the total canonical energy-momentum tensor of the closed system is given by
\[
\Sigma_i^j := \Sigma_i^j + \Sigma_i^j^{\text{em}},
\] (9.2)

with the electromagnetic part \( \Sigma_i^j^{\text{em}} \) given in Eqs. (8.2) and (8.4) and the material part \( \Sigma_i^j \) given in Eq. (7.7).

In order to find an explicit expression for the total canonical energy-momentum tensor \( \Sigma_i^j \), we first need to evaluate the variations \( \delta \Sigma_i^m / \delta u^j \), \( \delta \Sigma_i^m / \delta u^t \), and \( \delta \Sigma_i^m / \delta N^i \) and then insert them in Eqs. (7.9) and (7.10). For this aim, we take into account the equations of motion of the material variables
\[
\frac{\delta \Sigma_i^m}{\delta u^t} + \frac{\delta \Sigma_i^m}{\delta u^j} = 0,
\] (9.3)

\[
\frac{\delta \Sigma_i^m}{\delta u^j} + \frac{\delta \Sigma_i^m}{\delta N^i} = 0,
\] (9.4)

\[
\frac{\delta \Sigma_i^m}{\delta N^j} + \frac{\delta \Sigma_i^m}{\delta \Sigma_i^j} = 0,
\] (9.5)

from where we clearly see that the variations of the matter Lagrangian are exactly the negative of the variations of the electromagnetic Lagrangian, which we have already explicitly computed in Eqs. (8.8) and (8.9). In addition, the variation of the electromagnetic Lagrangian with respect to the particle number density \( \nu \), explicitly yields
\[
\frac{\delta \Sigma_i^m}{\delta \nu} = -\frac{1}{2} \left( \frac{\partial \Sigma_i^m}{\partial v} c^2 \right) + \frac{1}{\mu_0 \mu_\perp} \frac{\partial \Sigma_i^m}{\partial v} B^2 \\
+ \frac{1}{2} \left( \frac{\partial \Sigma_i^m}{\partial v} (\Sigma_i^m N^j)^2 - \frac{1}{\mu_0} \frac{\partial \Sigma_i^m}{\partial v} \left( B_j N^j \right)^2 \right),
\] (9.6)

where we defined the 4-vectors electric field \( \Sigma_i^m \) and magnetic field \( B^2 \) in Eqs. (5.31) and (5.32), respectively.

The variation (9.6) enters in the expression of the “effective” pressure (7.9), which include the terms describing the electrostriction and magnetostriction effects. Then, replacing the negative of the three variations (8.8), (8.9), and (9.6) into (7.7), (7.9), and (7.10), we explicitly obtain
\[
\sum_i^{\text{eff}} = \sum_i^{\text{eff}} + u^i \tilde{P}_i - \sum_i^{\text{eff}} + u^i F_{i k} F_i^k \frac{1}{c^2} \left( \frac{\partial \Sigma_i^m}{\partial v} c^2 \right) + \frac{1}{\mu_0 \mu_\perp} \frac{\partial \Sigma_i^m}{\partial v} B^2 \\
+ \frac{1}{\mu_0 \mu_\perp} \frac{\partial \Sigma_i^m}{\partial v} \left( B_j N^j \right)^2
\] (9.7)

where we denoted
\[
\tilde{P}_i := \frac{1}{c^2} u_i (\rho - J_\nu \omega^2 / 2) + \sum_i^{\text{eff}} + u^i F_{i k} F_i^k \frac{1}{c^2} \left( \frac{\partial \Sigma_i^m}{\partial v} c^2 \right) + \frac{1}{\mu_0 \mu_\perp} \frac{\partial \Sigma_i^m}{\partial v} B^2 \\
+ \frac{1}{\mu_0 \mu_\perp} \frac{\partial \Sigma_i^m}{\partial v} \left( B_j N^j \right)^2)
\] (9.8)

\[
\phi_i := \frac{\partial}{\partial \Sigma_i^m} \left( J_\nu u^k P_i^{k j} N_j \right) - \frac{\delta \Sigma_i^m}{\delta \Sigma_i^m},
\] (9.9)

The definitions of \( T_i^j \) and \( \rho^{\text{eff}} \) are given in Eqs. (7.8) and (7.9), respectively. Finally, if we consider (8.2), (8.4), and (9.7), we can write the total canonical tensor (9.2) explicitly, which reads
\[
+ \frac{1}{\mu_0} \Delta \mu^{-1} \left[ - F^{ij} N_k F_{iN} N_j^l + \frac{1}{2} \delta^j_i (F_{kN} N_j^l)^2 + N^j F_{iN} F^{kl} N_j + \frac{1}{c^2} N_i u^j u^k F_{iN} F^{lm} N_m \right] + \frac{1}{\mu_0 c^2} (\Delta \varepsilon + \Delta \mu^{-1}) (F_{pN} N^p u^q) \left[ N^j F_{iN} u^n + \left( - \frac{1}{2} \delta^j_i + \frac{1}{c^2} u^j u^l \right) (F_{kN} N^i N^l) \right] + H^i (\partial_k A_j). \tag{9.10}
\]

Since we already checked that the angular momentum balance equations are fulfilled both for the matter and electromagnetic parts of the total closed system in Eqs. (7.29) and (8.10), respectively, it is obvious that if we add both equations, then the angular balance equation for the total system will be also valid,

\[
\Sigma_{ij} + \partial_k S_{ij}^k = 0, \tag{9.11}
\]

where

\[
S_{ij}^k := \frac{m}{c^2} S_{ij}^k + \frac{c m}{c^2} S_{ij}^k. \tag{9.12}
\]

It is worthwhile to notice that the right-hand side of (9.11) vanishes since the total system is closed; however, the total energy-momentum tensor (9.10) is not symmetric, since the spin density of the system (9.12) is nontrivial.

**X. FULLY EXPPLICIT ENERGY-MOMENTUM CONSERVATION LAW**

The total system under consideration, composed of a relativistic liquid crystal plus electromagnetic field, is a closed system. There are no external fields present like \( J_{\text{ext}} \) and therefore the total canonical energy-momentum tensor (9.10) of the system is conserved:

\[
\partial_j \Sigma_{ij} = 0. \tag{10.1}
\]

Notice that in the expressions (7.12), (8.5), and (9.10)–(9.12), we have obtained the total energy-momentum tensor of the system and the identity of total angular momentum of the system, but without using a specific expression for the potential function \( \mathcal{V} = \mathcal{V}(N^i, \partial_j N^i, u^j) \). As a consequence, all the latter expressions are valid for an anisotropic uniaxial diamagnetic and dielectric medium, with any internal dynamics for the 4-director field \( N^i \). By considering the expression (6.4) for the Frank potential \( \mathcal{V} \), one can derive explicit expressions of the derivatives \( \partial \mathcal{V}/\partial u^j \), \( \partial \mathcal{V}/\partial (\partial_j N^i) \), \( \partial \mathcal{V}/\partial N^i \) and of the tensors \( T^i_{jk} \), \( S_{ij}^k \). This is done in detail in the Appendix.

In order to obtain an explicit expression of this conservation law, we can insert (9.8), (9.9), (7.13), (7.15), and (7.16) into (9.10). Due to the macroscopic Maxwell equations (5.2), the gauge noninvariant term in Eq. (9.10) vanishes and we finally obtain

\[
\partial_j \Sigma_{ij} + \partial_j \Sigma_{ij} = 0. \tag{10.2}
\]

Here the nonsymmetric energy-momentum tensor \( \Sigma_{ij} \) only depends on the material variables, as if the relativistic liquid crystal were in isolation.
XI. RELATIVISTIC DIRECTOR DYNAMICS

Let us analyze the equations of motion for the director \( N^i \). Rewriting equations (6.36) or (7.22), we have

\[
\pi^i \left[ \partial_k \left( J \nu u^k P_j^i N_l + h_j \right) + h_j \right] = 0, \tag{11.1}
\]

where we defined

\[
h_j : = - \frac{\delta \mathcal{L}^{\text{em}}}{\delta N^j} + \frac{\partial \mathcal{L}^{\text{em}}}{\partial N^j}, \tag{11.2}
\]

as the total 4-molecular field, since its spatial components reduce, in the nonrelativistic limit, to the standard “molecular field” \([1,16]\). In Sec. XII we study this limit in more detail. In order to better interpret the dynamics of \( N^i \), we can contract (11.1) with \( \epsilon^{pq} N_q \), make use of (A6) and the continuity equation (6.19), to obtain

\[
J \nu \pi^i \dot{\omega}^i = - \epsilon^{ijk} N_j h_k. \tag{11.3}
\]

From (11.3) we see that the 4-molecular field \( h_i \) is responsible for the “torques" and changes in the 4-director \( N^i \) of the liquid crystal. We can define two contributions to the 4-molecular field \( h_i = h_i^0 + h_i^\text{em} \). One is the Frank deformation 4-molecular field

\[
h_i^0 : = - \frac{\delta \mathcal{L}^{\text{em}}}{\delta N^i}, \tag{11.4}
\]

\[
= \partial_i \left[ K_1 (\delta_k N^k \delta_j^i + K_2 P_k^i P_j^k (\delta_k N_l - \delta_l N_k) + (K_3 - K_2) N^l (\delta^i N_l - \delta_l N^i)) + (K_3 - K_2) (\delta_k N^k (N^p \delta_p N_q)) P_q^i \right], \tag{11.5}
\]

which describes the changes in \( N^i \) caused by the deformations of the liquid crystal itself, and the other contribution is the electromagnetic 4-molecular field

\[
h_i^\text{em} : = \frac{\partial \mathcal{L}^{\text{em}}}{\partial N^i}, \tag{11.6}
\]

\[
= \frac{1}{\mu_0} \Delta \mu^{-1} F_{ik} F^{kij} + \frac{1}{\mu_0 c^2} (\Delta \rho + \Delta \mu^{-1}) (N^p F_{pq} u^q) F_{ik} u^k, \tag{11.7}
\]

which describes the influence of the dynamical electromagnetic field on the orientation of the 4-director.

With the knowledge of (10.2), together with Eq. (11.3) for \( N^i \), the continuity equation \( \partial_i (\nu u^i) = 0 \) in Eq. (6.19) for \( u^i \), \( v \) and the Maxwell equations (5.2) for \( F_{ij} \), we can completely determine the dynamics and evolution of this system, composed of the relativistic liquid crystal with anisotropic optical properties interacting with the electromagnetic field.

XII. NONRELATIVISTIC LIMIT

Let us study the dynamics of the liquid crystal in the nonrelativistic limit, when the motion of the fluid is such that \( |v| \ll c \). In particular, this approximation can be applied when the liquid crystal is at rest in the laboratory frame. In the nonrelativistic limit, we expect consistency with the earlier results \([1,8,16,17]\), but first we need some technical preparations. The 4-velocity reads

\[
u^i = \gamma (1, v), \tag{12.1}
\]

and therefore we have for the components of the projector:

\[
P_{ab}^0 = \delta_a^b + \frac{v_a v_b}{c^2}, \quad P_a^0 = \gamma^2 v_a, \tag{12.2}
\]

\[
P_a^a = -\gamma^2 v^a, \quad P_a^b = \gamma^2 v^a v^b/c^2. \tag{12.3}
\]

Hereafter, the three-dimensional indices are raised and lowered by the Euclidean metric; in particular, \( v = v^a, v_a = \delta_{ab} v^b \), \( v^2 = \gamma^2 v_a v_a = \delta_{ab} v^a v^b \), etc. For the skew-symmetric tensor \((4.5)\) we find explicitly

\[
\epsilon^{abc} = \gamma \epsilon^{abc}, \quad \epsilon^{0abc} = \gamma \epsilon^{abc} v_0/c^2, \tag{12.4}
\]

\[
\epsilon_{abc} = -\gamma \epsilon_{abc}, \quad \epsilon_{0abc} = \gamma \epsilon_{abc} v_0/c^2. \tag{12.5}
\]

Taking into account the orthogonality conditions \((4.2)–(4.4)\), the 4-director \( N^i \) reads in components

\[
N_i = \left( \frac{(v \cdot n)}{c^2} n_i \right). \tag{12.6}
\]

Notice that the 3-vector \( n_i \), with Cartesian components \( n^a \), recovers its normalization \( n^2 = \delta_{ab} n^a n^b = 1 \) only in the nonrelativistic limit. In general, it satisfies \( n^2 = 1 + (v \cdot n)^2/c^2 \).

A. Nonrelativistic director dynamics to zeroth order in \( v/c \)

First we note that \( N_i \dot{\omega}_i = 0 \) in Eq. (11.3) and therefore we obtain

\[
J \nu P_i \dot{\omega}^i = - \epsilon^{ijk} N_j h_k. \tag{12.7}
\]

Then, inserting (12.1)–(12.6) into (12.7), we find the nonrelativistic equation for \( n^a \) to zeroth order in \( v/c \)

\[
J \nu \dot{\omega}_i = n \times h_i. \tag{12.8}
\]

Here,

\[
\dot{\omega}_i = n \times \frac{\partial^2 n}{\partial t^2}, \tag{12.9}
\]

is the angular acceleration of a liquid crystal fluid element to zeroth order in \( v/c \). The right-hand side of (12.8) is determined by the molecular field, \( h_i = h_i^0 + h_i^\text{em} \). The fluid part,

\[
h_i^0 = (K_1 - K_2)(\delta_k \delta_k n^b) + K_2 \delta_{ab} \nabla^2 n^b + (K_3 - K_2) \delta_{ab} \delta_{cd} (n^b n^c \delta_{e f} n^d) - (K_3 - K_2) \delta_{ab} \delta_{cd} (n^b n^c \delta_{e f} n^d), \tag{12.10}
\]

is the zeroth order Frank deformation molecular field (cf. the nonrelativistic equation \((2.147)\) of \([8]\)). The electromagnetic part of the molecular field can be computed by taking the nonrelativistic limit to zeroth order in \( v/c \) of (11.7), which explicitly reads

\[
h_i^\text{em} = \epsilon_0 \Delta \epsilon (E \cdot n) E - \mu_0^{-1} \Delta \mu^{-1} (B \cdot n) B + \mu_0^{-1} \Delta \mu^{-1} B^2 n. \tag{12.11}
\]

The result (12.11) looks slightly different from the usual electromagnetic molecular field of the nonrelativistic models \([1,8,17]\), since we use the fields \( E \) and \( B \) as the independent fields and not \( E \) and \( H \). One can, however, easily recover
the same formulas in a different disguise by making use of the inverse of the constitutive relations (2.2). Notice that the last term in Eq. (12.11) is proportional to the director \( n \) and therefore it does not contribute to the torque when replaced in the cross product of (12.8). Therefore, we can ignore this last term and redefine the electromagnetic molecular field to zeroth order in \( v/c \), as a sum of two terms, the electric molecular field \( h_e \), and the magnetic molecular field \( h_m \), given by

\[
\begin{align*}
h_e &= \varepsilon_0 \Delta \varepsilon (E \cdot n)E, \\
h_m &= -\frac{1}{\mu_0} \Delta \mu^{-1} (B \cdot n)B.
\end{align*}
\]  

Collecting together all the results of this section, the dynamics of the director \( n \) in the nonrelativistic limit, to zeroth order in \( v/c \), is described by

\[
J \nabla \times \frac{\partial^2 \mathbf{n}}{\partial t^2} = \mathbf{n} \times \dot{\mathbf{h}}_E + \mathbf{n} \times \dot{\mathbf{h}}_m + \mathbf{n} \times \dot{\mathbf{h}}_m^m, 
\]

where the molecular field has independent contributions from the Frank deformations and the interactions with electric and the magnetic fields.

### B. Nonrelativistic solutions

Let us assume that the electromagnetic field vanishes, so that \( h_e = h_m = 0 \).

Stewart in Sec. 2.5 of [8] describes some exact solutions of the equations of motion. One is an obvious constant director solution; the other is the static spherical solution and the twist solution [with the local coordinates \( x = (x^1, x^2, x^3) \)]:

\[
n^a = \frac{x^a}{r},
\]

\[
n^a = (\cos \theta, \sin \theta, 0), \quad \theta = c_1 x^3 + c_2.
\]

Here we notice that the static twist solution (12.16) can be generalized to a dynamical “plane wave” solution:

\[
n^a = (\cos \Theta, \sin \Theta, 0), \quad \Theta = c_0 t + c_1 x^3 + c_2,
\]

where \( c_0, c_1, c_2 \) are arbitrary constants. In this case, we explicitly have

\[
\frac{\partial^2 \mathbf{n}}{\partial t^2} = -(c_0)^2 \mathbf{n},
\]

\[
\dot{h}_m^m = -K_2(c_1)^2 \mathbf{n},
\]

and thus (12.14) is satisfied. In the literature, the wave solutions of the full nonlinear equations of motion has attracted some attention (see [16,17,56]).

### XIII. SUMMARY AND DISCUSSION: ABRAHAM-MINKOWSKI CONTROVERSY

In this paper, we have constructed a complete relativistic Lagrangian theory of a nematic liquid crystal. Our results provide a consistent relativistic model for a medium with anisotropic optical properties in interaction with the electromagnetic field. In particular, in such a framework one can study the problem of the proper description of the energy and momentum of light in anisotropic media. This should shed light on the long standing Abraham-Minkowski controversy, traditionally discussed only for isotropic media.

We have generalized the earlier nonrelativistic model [16,17] and the variational model of an ideal relativistic fluid [26] and derived a complete theory of the nematic liquid crystal medium and its interaction with the electromagnetic field. We have derived the nonlinear equations of motion for the liquid crystal fluid, and explicitly verified the total energy, momentum and angular momentum balance laws, which arise as consequences of the Noether theorem from the invariance of the (field plus matter) system under space-time translations and Lorentz transformations, respectively. In this work the general formalism is presented in full detail. We will analyze the solutions and applications separately. The analysis of the properties of electromagnetic waves in the moving liquid crystal will be also considered elsewhere.

As we have seen, liquid crystals are an interesting example of continuous media with microstructure. The “internal” degrees of freedom of such a medium is represented by the director vector field \( N^a \) assigned to every material point of the fluid. This field gives rise to a nontrivial spin of the medium (7.17). As a consequence, the total energy-momentum tensor (9.2) of the closed system of the medium plus the electromagnetic field is not symmetric. This asymmetry is crucial for the validity of the Noether identities.

In this paper, we have neglected dissipation. The general formalism developed here is applicable to any moving medium with uniaxial anisotropic properties. In particular, one should have in mind possible astrophysical applications [54], where our model provides an explicit dynamical mechanism for the description of a physical medium with uniaxial anisotropy. As concerns the liquid crystals which belong to the class of moving uniaxial media, they are characterized by a nontrivial dissipation. In this sense, our theory has limited applicability and it should be considered only as a first step in constructing a full realistic physical model. The relativistic mechanics of dissipative fluids has a long and controversial history, with the first attempts going back to Eckart [57] and Landau-Lifshitz [58]. Later an essential improvement was achieved in the works of Israel and Stewart [59,60]. However, these models used a phenomenological approach with numerous ad hoc assumptions, and it seems more appropriate to use the approach of Carter [61–63], which generalizes the variational principle by replacing the Lagrangian with the so-called master function that systematically takes into account the irreversible viscosity and thermal effects. The development of the Carter type approach for dissipative media with microstructure will constitute the next step for the construction of the variational theory of liquid crystals. An important feature is that the Noether type identities play a central role in Carter’s approach.

Our current results contribute to the discussion of the energy and momentum problem of the electromagnetic field in a medium. In particular, our analysis clearly demonstrates that for the case of an uniaxial anisotropic medium it is the total energy-momentum tensor of the coupled system (matter plus field) that is important for the understanding of the balance of the momentum and angular momentum. For the case of an isotropic medium, this was pointed out more that 40 years ago by Penfield and Haus [28,29] and more recently in Refs. [26,27,30].

031703-14
Notwithstanding this general fact of the importance of the total energy momentum, one can split it into a “matter” and a “field” part in many different ways. Specifically, by expressing (9.10) in terms of $N^i$, $u^i$, $F_{jj}$, permeabilities and impermeabilities, we have shown that there exists a split of the form (10.3) plus (10.5). The purely matter part (10.3) does not depend explicitly on the field strength $F_{jj}$, except for the terms present in effective pressure. Therefore, it could be identified with what is sometimes called a “kinetic” energy momentum [31,32]. The corresponding field part (10.5) has a form which is more complicated than the usual Abraham tensor for isotropic media [26], since the former involves not only the field $F_{jj}$, the 4-velocity $u^i$, the isotropic permittivity $\varepsilon$ and the permeability $\mu$, but also the 4-director $N^i$, its derivatives, and the anisotropies $\Delta \varepsilon$, $\Delta \mu^{-1}$. Despite the fact that its structure is different from that of Abraham, this tensor plays a role analogous to that of the traditional Abraham tensor, namely reduces to it in the case $\Delta \varepsilon = \Delta \mu^{-1} = 0$.

However, the tensor (10.5) is not symmetric. It was pointed out in Ref. [26] that, for simple media where the 4-velocity $u^i$ is the only nonscalar field contained in the constitutive relation, the total energy-momentum tensor turns out to be the sum of a kinetic term plus the Abraham tensor. It was not clear whether this is the case for anisotropic media. Our results now would certainly improve our understanding of the Abraham-Minkowski controversy, which has been restricted only to simple media. Results in this direction will be analyzed in a forthcoming publication.

APPENDIX: EXPLICIT CALCULATION OF THE FRANK POTENTIAL TERMS

In this Appendix the explicit derivatives of the Frank potential are computed and an explicit verification of the Noether identity (7.28) is given. For the computation of the derivatives of the Frank potential (6.4), the following identities will be useful:

$$\epsilon_{ijk} N^i \epsilon^{pqk} \equiv P^p_j N^q_j - P^p_j P^q_j, \quad (A1)$$

$$P^j_i N^j_i \equiv N^i, \quad (A2)$$

$$N^i \epsilon^{pqr} = N^p \epsilon^{qr} + N^q \epsilon^{pr} + N^r \epsilon^{pq}, \quad (A3)$$

where $P^p_j$ and $\epsilon_{ijk}$ are defined in Eqs. (6.7) and (4.5), respectively. Then, using (A1)–(A3), we can prove these other useful relations:

$$\epsilon_{ijk} N^i \epsilon^{pqk} \equiv P^p_j N^q_j = P^p_j N^q_j \partial_i N^i, \quad (A4)$$

$$P^j_i N^j_i = \epsilon^{pq} \partial_q \partial_q N^i, \quad (A5)$$

$$2N_{[k} \epsilon_{ij]} \epsilon^{kl} N^l = -\epsilon_{klm} \partial^a N^m = 2N_{[k} P^l_j \partial_l N^j. \quad (A6)$$

We now are in condition to compute the contribution of the Frank potential to the dynamics of the fluid. For this, it is convenient to separate the potential (6.4) into three pieces:

$$\mathcal{V} := \mathcal{V}_1 + \mathcal{V}_2 + \mathcal{V}_3. \quad (A7)$$

1. The first elastic constant

For the splay deformation elastic potential,

$$\mathcal{V}_1 = \frac{1}{2} K_1 (\partial_i N^i)^2, \quad (A8)$$

we find

$$\partial \mathcal{V}_1 \partial \mathcal{V}_i = \partial \mathcal{V}_j \partial \mathcal{V}_j = 0, \quad (A9)$$

$$\partial \mathcal{V}_1 \partial \mathcal{V}_j = K_1 (\partial_k N^k \partial_j N^j), \quad (A10)$$

Then, using (A9)–(A11) in Eq. (7.8), we obtain

$$T^j_i = -K_1 (\partial_k N^k \partial_j N^j ) + \delta^j_i \mathcal{V}_1, \quad (A12)$$

$$2 T^j_{[i]j] = -K_1 (\partial_k N^k \partial_j N^j + \partial_j N^j \partial_k N^k). \quad (A13)$$

Finally, let us calculate explicitly the terms

$$\frac{\partial \mathcal{V}_1}{\partial \mathcal{V}_j} \partial \mathcal{V}_j = -K_1 (\partial_k N^k \partial_j N^j), \quad (A14)$$

$$-\partial_k \left( N^j \frac{\partial \mathcal{V}_1}{\partial \mathcal{V}_j} \right) = -K_1 (\partial_k N^k \partial_j N^j) - K_1 N^j \partial_j N^j. \quad (A15)$$

Substituting all this into (7.28), we verify the Noether identity for $\mathcal{V}_1$.

2. The second elastic constant

The second term (twist deformation) in the Frank potential is given by

$$\mathcal{V}_2 = \frac{1}{2} K_2 (\epsilon^{ijk} N_j \partial_j N_k)^2. \quad (A16)$$

Using the identities (A1) and (A3), we can rewrite this as

$$\mathcal{V}_2 = \frac{1}{2} K_2 \left[ \epsilon^{ijk} N_j \partial_j N_k \partial_k N^j \partial_j N^k \right] = \frac{1}{2} K_2 \left[ P^k_j P_j \partial_k N^j (N^q \partial_q N^k) \right]. \quad (A17)$$

The derivatives of the potential $\mathcal{V}_2$ with respect to the director and its derivatives are straightforwardly calculated.
\[ \frac{\partial V_2}{\partial N^j} = -K_2(\partial_i N^p)(N^k \partial_k N_q)P^q_{\ p} \]

\[ = K_2(\partial_i N^k)(N^p \partial_p N_q) - \frac{K_2}{c^2}(\partial_i N^p)u_p(N^q \partial_q N^k)u_k, \]  

(A19)

\[ \frac{\partial V_2}{\partial \partial_j N^i} = K_2\left [ P_k^j \left ( \partial^k N_l - \partial_l N^k \right ) + N^j P_k^i \left ( N^p \partial_p N_q \right ) \right ] \]

\[ = K_2\left ( \partial^j N_l - \partial_l N^j + N^j \partial_l N_i \right ) - \frac{K_2}{c^2} \left [ u_l(\dot{N}^i - u^k \partial_k N_l) - u_i(\dot{N}^j - u^k \partial_k N_i) \right ] + N^j u_l(N^p \partial_p N^k)u_k. \]  

(A20)

In addition, the derivative with respect to the velocity reads

\[ \frac{\partial V_2}{\partial \dot{u}^i} = -\frac{K_2}{c^2} \left [ (\partial_i N_j - \partial_j N_i)(\dot{N}^j - u^k \partial_k N_i) \right ] + (N^p \partial_p N^i)(N^q \partial_q N^k)u_k]. \]  

(A21)

Substituting (A20) into the definition (7.8), we obtain the contribution of \( K_2 \) to the energy-momentum tensor

\[ F^2_{ij} = \delta^i_j V_2 - K_2(\partial_i N_k)(P^j_p P^k_q(\partial^p N^q - \delta^q N^p)) + N^j P_k^i \left ( N^p \partial_p N^k \right ) \]

\[ = \delta^i_j V_2 - K_2(\partial_i N_k)(\partial^i N^k - \delta^i N^k + N^i \partial_j N_k) - \frac{K_2}{c^2}(\partial_i N_k)u_l(\dot{N}^k - u^j \partial_j N_l) - u^i(\dot{N}^j - u^k \partial_k N_i) + N^j u_l(N^p \partial_p N^i)u_k. \]  

(A22)

In order to check the Noether identity (7.28) for the \( V_2 \) term, we first notice that it can be identically recast into

\[ F^2_{[ij]} + \frac{\partial V_2}{\partial \dot{u}^i} u^i_{\ j} + \frac{\partial \partial V_2}{\partial N^i} N_j - (\partial_k N_j) \frac{\partial V_2}{\partial \partial_k N^i} = 0. \]  

(A24)

Using (A20), we derive an intermediate result:

\[ (\partial_k N_j) \frac{\partial V_2}{\partial \partial_k N^i} \]

\[ = K_2(\partial^k N_j)(\partial_k N_i - \partial_i N_k) + (N^p \partial_p N_j)(N^q \partial_q N_i)) - \frac{K_2}{c^2} \left [ u_l(\dot{N}^i - u^k \partial_k N_l) - u_i(\dot{N}^j - u^k \partial_k N_i) \right ] + u_i u^k(N^p \partial_p N^i)(N^q \partial_q N_k). \]  

(A25)

It is straightforward to find the antisymmetric objects using (A19), (A21), (A23), and (A25):

\[ F^2_{[ij]} = -K_2(\partial^k N_j)(\partial_j N_i) - \frac{K_2}{c^2} \left [ \dot{N}_i(\partial_j N_k)u_k - N^j \partial_i N_k \right ] \]

\[ + K_2 N_i(\partial_j N_k)(N^p \partial_p N_k) - \frac{K_2}{c^2} u_i(\partial_j N_k)(\dot{N}^k - u^l \partial_l N_i) - \frac{K_2}{c^2} \left [ N^k(\partial_j N_i)u_k(N^q \partial_q N_i)u^j, \right ] \]  

(A26)

\[ \frac{\partial V_2}{\partial u^i} u_{ij} = \frac{K_2}{c^2} u_i(\partial_j N_k)(\dot{N}^k - u^l \partial_l N_i) \]

\[ - \frac{K_2}{c^2} u_i(\partial^k N_j)(\dot{N}_k - \partial_l N_i) \]

\[ + \frac{K_2}{c^2} u_i N^p(\partial_p N_j)(N^q \partial_q N_k)u^k, \]  

(A27)

\[ \frac{\partial V_2}{\partial N^i} N_j = -K_2 N_i(\partial_j N_k)(N^p \partial_p N_k) \]

\[ + \frac{K_2}{c^2} N_i(\partial_j N^k)u_k(N^q \partial_q N_i)u^j, \]  

(A28)

and

\[ (\partial_k N_j) \frac{\partial V_2}{\partial \partial_k N^i} = \frac{K_2}{c^2} (\partial^k N_j)(\partial_k N_i) - \frac{K_2}{c^2} \dot{N}_i(\partial_j N_k)u_k \]

\[ - \frac{K_2}{c^2} u_i(\partial^k N_j)(\dot{N}_k - \partial_l N_i) \]

\[ + \frac{K_2}{c^2} u_i N^p(\partial_p N_j)(N^q \partial_q N_k)u^k. \]  

(A29)

Substituting this into (A24), we verify the Noether identity (7.28) for the second term \( V_2 \).

3. The third elastic constant

Analogously, we consider the third term (bend deformation) in the Frank potential,

\[ V_3 = -\frac{1}{2} K_3(N^i \dot{N}^j \delta^k \partial_k N_i)^2 \]

\[ = -\frac{1}{2} K_3 P^i_p(\partial^p N_i)(N^q \partial_q N^i), \]  

(A30)

where we have used (A4) to simplify the potential. It is worthwhile to notice that this quadratic invariant has the same form as the last term in the \( K_2 \) potential (A18). As a result, the corresponding derivatives of the potential (A30) with respect to its arguments can be conveniently extracted from the formulas (A19)–(A21). These derivatives are given by

\[ \frac{\partial V_3}{\partial N^i} = -K_3(\partial_i N^p)(N^k \partial_k N_q)P_q^p \]

\[ = -K_3(\partial_i N^k)(N^q \partial_q N_p) \]

\[ + \frac{K_3}{c^2}(\partial_i N^p)u_p(N^q \partial_q N^k)u_k, \]  

(A32)

\[ \frac{\partial V_3}{\partial \partial_j N^i} = -K_3 N^j P^i_p(\partial^p N_i) \]

\[ = -K_3 N^j N^p \partial_p N^i \]

\[ + \frac{K_3}{c^2} N^j u_p(N^q \partial_q N^k)u_k, \]  

(A33)

\[ \frac{\partial V_3}{\partial \dot{u}^i} = \frac{K_3}{c^2} (N^p \partial_p N_i)(N^q \partial_q N^k)u_k. \]  

(A34)

The stress tensor (7.8) for \( V_3 \) reads

\[ F^3_{ij} = \delta^i_j V_3 + K_3(\partial_i N_k)N_j P_k^i(\partial^p N_p N^i) \]

\[ = \delta^i_j V_3 + K_3(\partial_i N_k)N_j(\partial^p N_p N^k) \]

\[ - \frac{K_3}{c^2} (\partial_i N_k)N^i (\partial^p N_p N^k)u^k u_j. \]  

(A35)
In order to check the Noether identity for this last part of the potential \( \mathcal{V} \), we observe that Eqs. (A33)–(A38) yield

\[
\frac{\partial \mathcal{V}_3}{\partial N_{ij}} N_{ij} = -K_3 N_{ij} (\partial_j N^k) (N^p \partial_p N_k) + \frac{K_3}{c^2} N_{ij} (\partial_j N^k) u_k (N^q \partial_q N_i) u^l,
\]

\[
\frac{\partial \mathcal{V}_3}{\partial u^{(j)}} u^{(j)} = -\frac{K_3}{c^2} u^{(j)} N_{ij} (\partial_j N^k) u_k (N^q \partial_q N_i) u^k,
\]

where \( K_3 \) is a constant. Substituting all this into (A24), we verify the Noether identity (7.28) for the third term \( \mathcal{V}_3 \).
